# Expressiveness of RNNs

# Expressiveness of RNNs

Good news: RNNs are universal approximators.

(Schäfer and Zimmermann, 2006)

Consider a finite-horizon dynamical system

$$\mathbf{x}_k = f(\mathbf{x}_{k-1}, \mathbf{u}_k),$$

$$\mathbf{y}_k = g(\mathbf{x}_k),$$

where  $f$  is measurable and  $g$  is continuous. It is arbitrarily close (in the operator sense) to an RNN with a potentially larger latent state-space dimension (i.e., the size of  $\mathbf{x}$ ).

# Expressiveness of RNNs

Good news: RNNs are universal approximators.

# Why Do We Observe Vanishing/Exploding Gradients?

# Why Do We Observe Vanishing/Exploding Gradients?

The memory of an input is dampened or magnified by a constant factor.

$$\rho(W) > 1$$

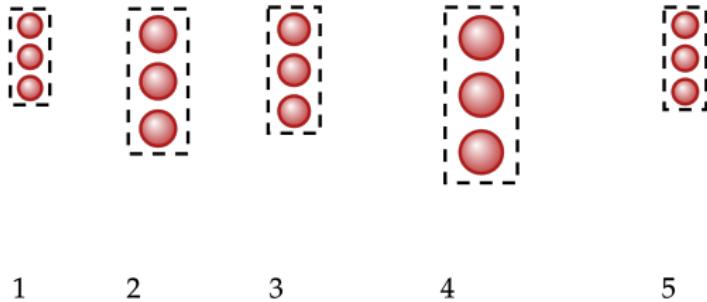

$$\rho(W) < 1$$

# Why Do We Observe Vanishing/Exploding Gradients?

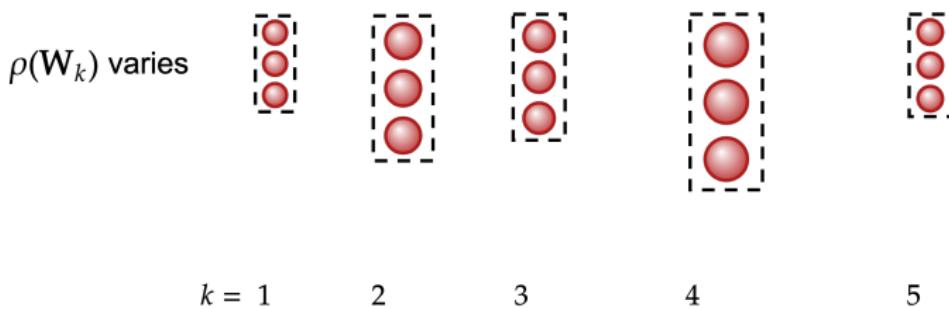

If we can make the memory decay or amplify differently at every step, then we can reduce the vanishing/exploding gradient issues.

$\rho(W_k)$  varies

# Why Do We Observe Vanishing/Exploding Gradients?

If we can make the memory decay or amplify differently at every step, then we can reduce the vanishing/exploding gradient issues.

This is partially why a deep MLP does not suffer from such issues. Unfortunately, we cannot train a different  $\mathbf{W}_k$  for each step  $k$ . We need to be smarter in constructing the recurrent unit.

# Gated Recurrent Unit

Gated recurrent units (GRUs) [Cho et al., 2014] are similar to LSTMs in many sense.

$$\begin{aligned} \mathbf{x}_k &= (1 - \mathbf{z}_k) \circ \mathbf{x}_{k-1} + \mathbf{z}_k \circ \tilde{\mathbf{x}}_k, \\ \mathbf{z}_k &= \sigma(\mathbf{W}_z \mathbf{x}_{k-1} + \mathbf{U}_z \mathbf{u}_k + \mathbf{b}_z), \\ \tilde{\mathbf{x}}_k &= \tanh(\mathbf{W}_x (\mathbf{r}_k \circ \mathbf{x}_{k-1}) + \mathbf{U}_x \mathbf{u}_k + \mathbf{b}_x), \\ \mathbf{r}_k &= \sigma(\mathbf{W}_r \mathbf{x}_{k-1} + \mathbf{U}_r \mathbf{u}_k + \mathbf{b}_r), \end{aligned}$$

# Transformers

# Transformers

Transformers form a class of models that are wildly used in NLP and CV.

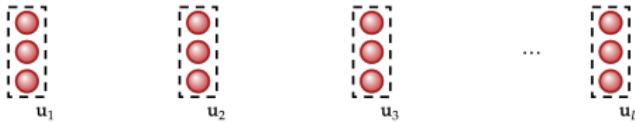

[Vaswani et al.,  
2017]

# Transformers

The backbone of a transformer is called the attention mechanism.  
Compared to recurrent models, attention explicitly seeks a connection  
between every pair of elements in a sequence.

# Transformers

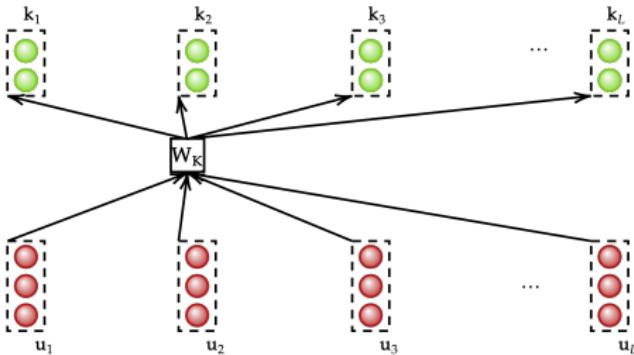

The backbone of a transformer is called the attention mechanism.  
Compared to recurrent models, attention explicitly seeks a connection  
between every pair of elements in a sequence.

# Transformers

The backbone of a transformer is called the attention mechanism.  
Compared to recurrent models, attention explicitly seeks a connection  
between every pair of elements in a sequence.

$$\mathbf{k}_i = \mathbf{W}_K \mathbf{x}_i,$$

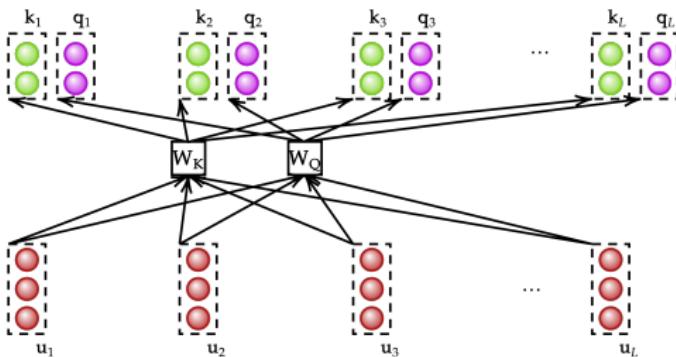

# Transformers

The backbone of a transformer is called the attention mechanism.  
Compared to recurrent models, attention explicitly seeks a connection  
between every pair of elements in a sequence.

$$\mathbf{k}_i = \mathbf{W}_k \mathbf{x}_i,$$

$$\mathbf{q}_i = \mathbf{W}_q \mathbf{x}_i,$$

Then, why doesn't an SSM suffer from the vanishing and exploding  
gradient issues?

# Training Stability of SSMs

The gradient is the gradient. It doesn't matter how you compute it.  
Then, why doesn't an SSM suffer from the vanishing and exploding  
gradient issues?

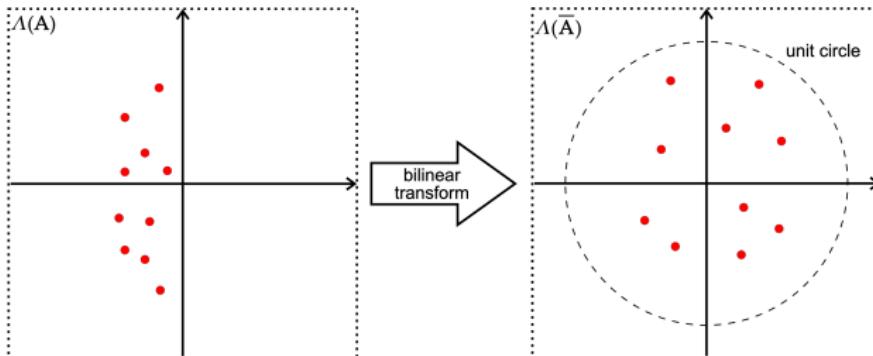

Answer: by discretizing the system with a small  $\Delta t$ !

# Training Stability of SSMs

The gradient is the gradient. It doesn't matter how you compute it.  
Then, why doesn't an SSM suffer from the vanishing and exploding gradient issues?

Answer: by discretizing the system with a small  $\Delta t$ !

- By restricting  $\Lambda(\mathbf{A})$  in the left half-plane, we guarantee that  $\rho(\overline{\mathbf{A}}) < 1$ .

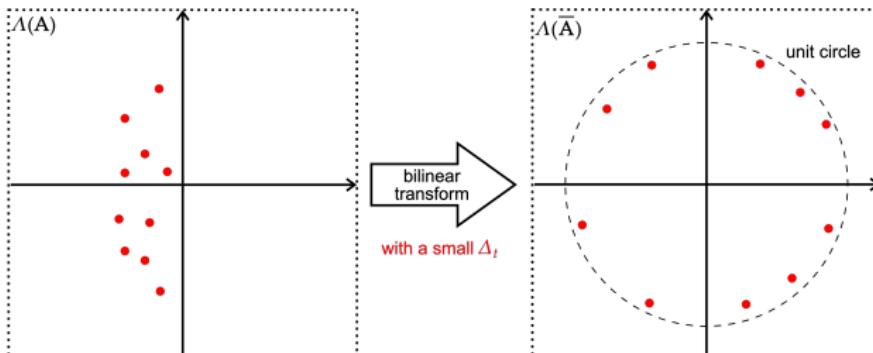

# Training Stability of SSMs

The gradient is the gradient. It doesn't matter how you compute it.

## Mambas

SSMs are good at learning tasks that involve long-range dependencies, but their vanilla forms do not lead to good language models.

One of the reasons is that in an SSM, every element in a sequence is processed using the same mechanism. The Mamba models [Gu and Dao, 2023] fix this issue by letting **B** and **C** depend on the input.

# Mambas

# Linear, Time-Invariant Systems

A state space model (SSM) [Gu et al., 2022] leverages linear, time-variant (LTI) systems as its recurrent unit:

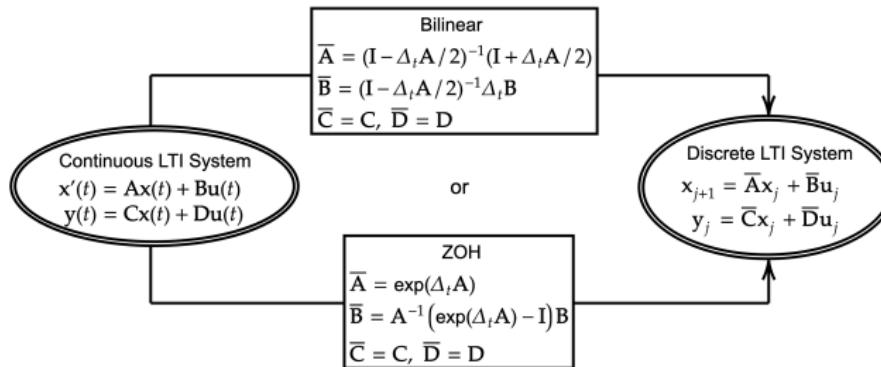

$$\begin{aligned}\mathbf{x}'(t) &= \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t), \\ \mathbf{y}(t) &= \mathbf{C}\mathbf{x}(t) + \mathbf{D}\mathbf{u}(t).\end{aligned}$$

# Linear, Time-Invariant Systems

A state space model (SSM) [Gu et al., 2022] leverages linear, time-variant (LTI) systems as its recurrent unit:

$$\begin{aligned} \mathbf{x}'(t) &= \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t), \\ \mathbf{y}(t) &= \mathbf{C}\mathbf{x}(t) + \mathbf{D}\mathbf{u}(t). \end{aligned}$$

We have to discretize the system with respect to some trainable sampling period  $\Delta t > 0$ :

## Overview of the Next Two Parts

## Overview of the Next Two Parts

We saw that one can compute an LTI system from its transfer function:

$$\hat{\mathbf{y}}(s) = \mathbf{G}(is)\hat{\mathbf{u}}(s), \quad \mathbf{G}(is) = \mathbf{C}(is\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}.$$

## Overview of the Next Two Parts

We saw that one can compute an LTI system from its transfer function:

$$\hat{\mathbf{y}}(s) = \mathbf{G}(is)\hat{\mathbf{u}}(s), \quad \mathbf{G}(is) = \mathbf{C}(is\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}.$$

A key question is: how can we efficiently sample  $\mathbf{G}$ ?

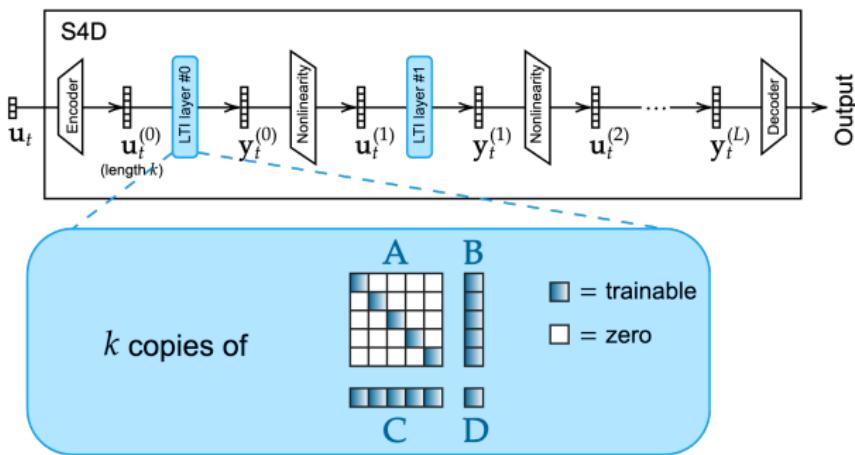

## Overview of the Next Two Parts

We saw that one can compute an LTI system from its transfer function:

$$\hat{\mathbf{y}}(s) = \mathbf{G}(is)\hat{\mathbf{u}}(s), \quad \mathbf{G}(is) = \mathbf{C}(is\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}.$$

A key question is: how can we efficiently sample  $\mathbf{G}$ ?

From now on, we assume that an LTI system is single-input/single-output (SISO). Moreover, the matrix  $\mathbf{A}$  is diagonal.

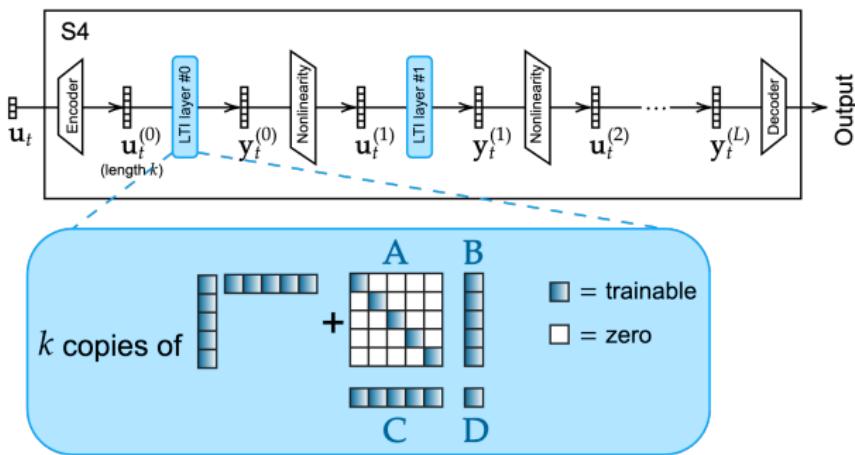

## Overview of the Next Two Parts

We saw that one can compute an LTI system from its transfer function:

$$\hat{\mathbf{y}}(s) = \mathbf{G}(is)\hat{\mathbf{u}}(s), \quad \mathbf{G}(is) = \mathbf{C}(is\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}.$$

A key question is: how can we efficiently sample  $\mathbf{G}$ ?

From now on, we assume that an LTI system is single-input/single-output (SISO). Moreover, the matrix  $\mathbf{A}$  is diagonal.

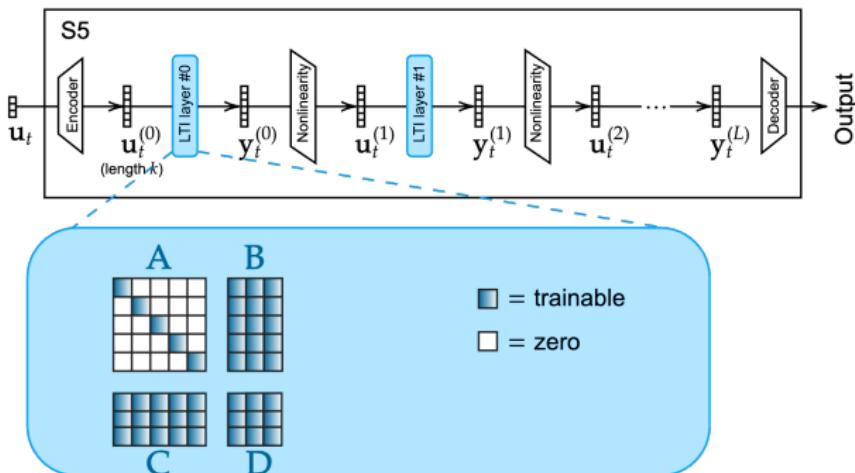

## Overview of the Next Two Parts

We saw that one can compute an LTI system from its transfer function:

$$\hat{\mathbf{y}}(s) = \mathbf{G}(is)\hat{\mathbf{u}}(s), \quad \mathbf{G}(is) = \mathbf{C}(is\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}.$$

A key question is: how can we efficiently sample  $\mathbf{G}$ ?

From now on, we assume that an LTI system is single-input/single-output (SISO). Moreover, the matrix  $\mathbf{A}$  is diagonal.

# Two Weaknesses of SSMs

## Two Weaknesses of SSMs

- ① From a random matrix theory perspective, high-rank LTI systems are scarce. Hence, even with a proper initialization, one can easily lose numerical ranks during training.

# Two Weaknesses of SSMs

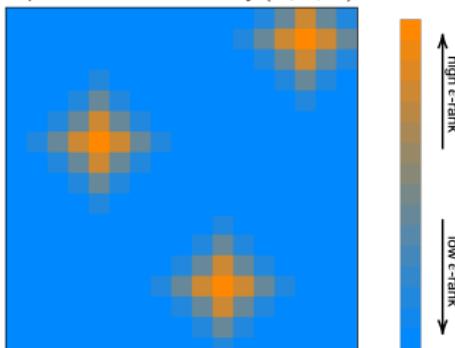

- ① From a random matrix theory perspective, high-rank LTI systems are scarce. Hence, even with a proper initialization, one can easily lose numerical ranks during training.

The  $\epsilon$ -rank of a random LTI system, i.e., the number of Hankel singular values  $\sigma_j$  with

$$\frac{\sigma_j}{\sigma_1} > \epsilon,$$

is roughly  $\mathcal{O}(n^{1/2+a} \text{ bit})$  with high probability.

Space Parameterized by  $(A, B, C)$

# Two Weaknesses of SSMs

is roughly  $\mathcal{O}(n^{1/2+a} \text{ bit})$  with high probability.

Space Parameterized by  $(A, B, C)$

## Two Weaknesses of SSMs

- ② The numerical stability of an LTI system depends on its parameters, making an SSM potentially not numerically stable over training.

## Two Weaknesses of SSMs

- ② The numerical stability of an LTI system depends on its parameters, making an SSM potentially not numerically stable over training.

When an LTI system is perturbed with

$$\|\mathbf{A} - \tilde{\mathbf{A}}\|_{\max} \leq \Delta_A, \quad \|\mathbf{B} \circ \mathbf{C}^\top - \tilde{\mathbf{B}} \circ \tilde{\mathbf{C}}^\top\|_{\max} \leq \Delta_B.$$

The transfer function perturbation can be bounded by

$$\|G - \tilde{G}\|_\infty \leq n\Delta_B \max_j \frac{1}{|\operatorname{Re}(a_j)|} + 4n\Delta_A \max_j \frac{|b_j c_j|}{|\operatorname{Re}(a_j)|^2}.$$

Moreover, this bound is tight up to a factor of  $n$ .

## Two Weaknesses of SSMs

- ② The numerical stability of an LTI system depends on its parameters, making an SSM potentially not numerically stable over training.

When an LTI system is perturbed with

$$\|\mathbf{A} - \tilde{\mathbf{A}}\|_{\max} \leq \Delta_A, \quad \|\mathbf{B} \circ \mathbf{C}^\top - \tilde{\mathbf{B}} \circ \tilde{\mathbf{C}}^\top\|_{\max} \leq \Delta_B.$$

The transfer function perturbation can be bounded by

$$\|G - \tilde{G}\|_\infty \leq n\Delta_B \max_j \frac{1}{|\operatorname{Re}(a_j)|} + 4n\Delta_A \max_j \frac{|b_j c_j|}{|\operatorname{Re}(a_j)|^2}.$$

Moreover, this bound is tight up to a factor of  $n$ .

“[the Hankel singular values] decay more rapidly the farther the  $\Lambda(\mathbf{A})$  falls in the left half of the complex plane.” — [Baker et al., 2015]

# Why Do SSMs Have Frequency Bias?

- An SSM is initialized with frequency bias.

# Why Do SSMs Have Frequency Bias?

- An SSM is initialized with frequency bias.
- Will training push the eigenvalues of  $\mathbf{A}$  to the high-frequency region?

# Why Do SSMs Have Frequency Bias?

- An SSM is initialized with frequency bias.
- Will training push the eigenvalues of  $\mathbf{A}$  to the high-frequency region?

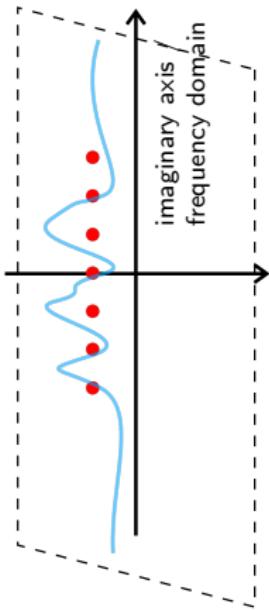

The gradient of a generic loss  $\mathcal{L}$  with respect to  $\text{Im}(a_j)$  satisfies

$$\frac{\partial \mathcal{L}}{\partial \text{Im}(a_j)} = \int_{-\infty}^{\infty} \frac{\partial \mathcal{L}}{\partial \mathbf{G}(is)} \cdot K_j(s) \, ds,$$
$$|K_j(s)| = \mathcal{O}(|s - \text{Im}(a_j)|^{-2}).$$

# Why Do SSMs Have Frequency Bias?

- An SSM is initialized with frequency bias.
- Will training push the eigenvalues of  $\mathbf{A}$  to the high-frequency region?

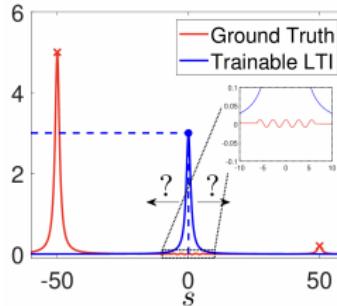

The gradient of a generic loss  $\mathcal{L}$  with respect to  $\text{Im}(a_j)$  satisfies

$$\frac{\partial \mathcal{L}}{\partial \text{Im}(a_j)} = \int_{-\infty}^{\infty} \frac{\partial \mathcal{L}}{\partial \mathbf{G}(is)} \cdot K_j(s) \, ds,$$

$$|K_j(s)| = \mathcal{O}(|s - \text{Im}(a_j)|^{-2}).$$

Hence,  $a_j$  only learns “local” frequencies.

$$\hat{\mathbf{y}}(s) = (1 + |s|)^\beta \mathbf{G}(is)\hat{\mathbf{u}}(s).$$

Intuitively,  $\beta$  reweights the frequency domain.

- $\beta < 0 \Rightarrow$  low frequencies are weighted more, frequency bias is enhanced.
- $\beta > 0 \Rightarrow$  low frequencies are weighted less, frequency bias is diminished.

# Tuning Frequency Bias via Training

We can apply a Sobolev-norm-based filter to the transfer function:

$$\hat{\mathbf{y}}(s) = (1 + |s|)^{\beta} \mathbf{G}(is) \hat{\mathbf{u}}(s).$$

Intuitively,  $\beta$  reweights the frequency domain.

- $\beta < 0 \Rightarrow$  low frequencies are weighted more, frequency bias is enhanced.
- $\beta > 0 \Rightarrow$  low frequencies are weighted less, frequency bias is diminished.

Surprisingly,  $\beta$  also affects the training.

The gradient of a generic loss  $\mathcal{L}$  with respect to  $\text{Im}(a_j)$  satisfies

$$\frac{\partial \mathcal{L}}{\partial \text{Im}(a_j)} = \int_{-\infty}^{\infty} \frac{\partial \mathcal{L}}{\partial \mathbf{G}(is)} \cdot K_j^{(\beta)}(s) ds,$$
$$|K_j^{(\beta)}(s)| = \mathcal{O}(|s - \text{Im}(a_j)|^{-2+\beta}).$$

# Conclusion

**Conclusion:**

# Conclusion

## Conclusion:

- ➊ SSMs are linear RNNs that allow fast and numerically stable computation.

# Conclusion

## Conclusion:

- ① SSMs are linear RNNs that allow fast and numerically stable computation.
- ② Hankel singular values explain the success or failure of an SSM.  
HOPE gives a more robust parameterization.

# Conclusion

## Conclusion:

- ❶ SSMs are linear RNNs that allow fast and numerically stable computation.
- ❷ Hankel singular values explain the success or failure of an SSM. HOPE gives a more robust parameterization.
- ❸ Frequency bias helps avoid overgeneralization but also prevents us from learning high-frequency information. Consider changing the hyperparameters  $\alpha$  and  $\beta$  to tune frequency bias.

# Conclusion

## Conclusion:
